

TRANSFER DEVICE

ABSTRACT OF THE DISCLOSURE

A fluid transfer device collects fluid by capillary attraction into a housing and provides for the subsequent dispensing of the collected fluid. The fluid transfer device includes a housing defining a housing interior, and including an access port and elongate capillary channel in fluid communication with the access port and the housing interior. Fluid is drawn through the access port and into the capillary channel under capillary action. The housing is deformable so as to compress the housing interior and exert an expelling force on the capillary channel to expel the fluid from the access port.
